ABSTRACT OF THE DISCLOSURE

An internal memory uses a resource identifier and an entry point to identify which functional program from an external memory is to be loaded into one of a plurality of

5   overlay spaces established in the internal memory. In executing a program statement, the resource identifier identifies a corresponding functional program to perform a particular functional operation and the identified functional program is then loaded into an overlay space specified by the entry point. The functional program is then executed in the overlay space.
